A chain reaction happens when more and more edges are added to a graph. We consider only regular S_{mu} -cells, but we are able to prove [that] the same conclusions hold for all other S_{mu} -cells, even in the singular setting. For a curve SXS over an arbitrary base scheme SS , we define a relative moduli space $Smatheal[R]_{XS}$ consisting of morphisms $Sf: X$ to SS up to automorphism of SXS . In this paper, we study the deformation theory of some special classes of curves ("rigid curves") in $Smatheal[R]_{XS}$ with respect to a moduli problem. We will give the complete construction of the moduli space $Smatheal[R]_{XS}$ in the case when SXS has a kind of "pathological singularity", as opposed to the case when SXS has a log-smooth model, in which case this construction has already been done. Two curves are called projectively equivalent if there exists a projective transformation between them. In particular, if two cubic curves are projectively equivalent, then they are isomorphic. In this paper we study two types of cubics that are equivalent to each other: an elliptic curve SES and a nodal plane cubic SDS . Such a pair of curves $S(E,D)S$ is called a [Picard pair]. We prove that there are exactly $S10S$ Picard pairs of curves: three pairs of curves each of the types $S(E_{d,n}, E_{d,m})S$, $S(E_{d,n}, E_{n,m})S$ and $S(E_{d,n}, E_{n,n})S$, where SdS and Sn,mS are positive integers. The local structure of a cubic curve SXS is a point of infinite order in the automorphism group of SXS (a Weierstrass point). Two cubics SX_{1S} and SX_{2S} are said to be locally equivalent if $82157476af$
